

Def.: A one-particle irreducible (1PI) diagram cannot be split in two by removing a single line.

Example:  is 1PI,  is not.

$-i\Sigma(p)$ is the sum of all 1PI diagrams with two external lines.

$$-i\Sigma(p) = \leftarrow \textcircled{\text{1PI}} \leftarrow = \text{cloud on top} + \text{cloud on bottom} + \dots$$

We can now write $\int d^4x \langle 0 | T \psi(x) \bar{\psi}(0) | 0 \rangle e^{ipx}$

$$= \leftarrow + \leftarrow \textcircled{\text{1PI}} \leftarrow + \leftarrow \textcircled{\text{1PI}} \leftarrow \textcircled{\text{1PI}} \leftarrow + \dots$$

$$= \frac{i}{\not{p} - m_0 - \Sigma(\not{p})} \quad \text{see EX 5 \& EX 8}$$

Therefore: $[\not{p} - m_0 - \Sigma(\not{p})] |_{\not{p}=m} = 0$

$$\approx (\not{p} - m) \left(1 - \frac{d\Sigma}{d\not{p}} \Big|_{\not{p}=m} \right) = 1/z_2 + \mathcal{O}((\not{p} - m)^2)$$

Now we can finally calculate

$$S_m = m - m_0 = \Sigma_2(\not{p}=m) \approx \Sigma_2(\not{p}=m_0)$$

$$S_m = \frac{\alpha}{2\pi} m_0 \int_0^1 dx (2-x) \log \left(\frac{x\Lambda^2}{(1-x)^2 m_0^2 + x\mu^2} \right)$$

Diverges for $\Lambda \rightarrow \infty$:

$$S_m \xrightarrow{\Lambda \rightarrow \infty} \frac{3\alpha}{4} m_0 \log \left(\frac{\Lambda^2}{m_0^2} \right)$$

We will address this issue when we discuss renormalisation.

$$S z_2 = \frac{d\Sigma_2}{d\not{p}} \Big|_{\not{p}=m} = \frac{\alpha}{2\pi} \int_0^1 dx \left[-x \log \frac{x\Lambda^2}{(1-x)^2 m^2 + x\mu^2} \right.$$

$$\left. + 2(2-x) \frac{x(1-x)m^2}{(1-x)^2 m^2 + x\mu^2} \right]$$

Also log UV divergence.

6.3. Dimensional Regularisation

Idea: making divergent integral convergent by introducing a parameter

↳ different ways to do this might give different results for observables \rightarrow regulator breaks symmetry

choose regulator which is compatible with postulated sym.

We already encountered Pauli-Villars reg.
gauge invariant but not covariant \rightarrow fails for QCD

↳ dimensional regularisation

Idea: compute integrals as an analytic function of dimension, i.e from last lecture

$$I = \int \frac{d^d l_E}{(2\pi)^d} \frac{1}{(l_E^2 + \Delta)^2} = \underbrace{\int \frac{d\Omega_d}{(2\pi)^d}}_A \cdot \underbrace{\int_0^\infty dl_E \frac{l_E^{d-1}}{(l_E^2 + \Delta)^2}}_B$$

A) $\int d\Omega_d = \frac{2\pi^{d/2}}{\Gamma(d/2)}$ (surface area of d-dim unit sphere)

B) $= \frac{1}{2} \int_0^\infty d(l_E^2) \frac{(l_E^2)^{\frac{d}{2}-1}}{(l_E^2 + \Delta)^2} = \frac{1}{2} \left(\frac{1}{\Delta}\right)^{2-\frac{d}{2}} \int_0^1 dx x^{1-\frac{d}{2}} (1-x)^{\frac{d}{2}-1}$

$$x = \Delta / (l_E^2 + \Delta)$$

Trick: $\int_0^1 dx x^{\alpha-1} (1-x)^{\beta-1} = B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$

\downarrow
 $= \frac{1}{(4\pi)^{d/2}} \frac{\Gamma(2-\frac{d}{2})}{\Gamma(2)} \left(\frac{1}{\Delta}\right)^{2-\frac{d}{2}}$ expand around $d=4+\epsilon$

$$\Gamma\left(2 - \frac{d}{2}\right) = \Gamma(\epsilon/2) = \frac{2}{\epsilon} - \gamma + \mathcal{O}(\epsilon)$$

≈ 0.5772 *cancels in observables*

$$\lim_{d \rightarrow 4} I = \frac{1}{(4\pi)^2} \left(\frac{2}{\epsilon} - \log \Delta - \gamma + \log(4\pi) + \mathcal{O}(\epsilon) \right)$$

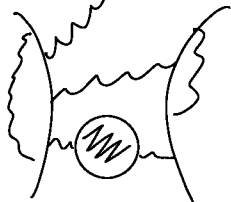

vs. Pauli-Villars from last lecture

$$\lim_{\Lambda \rightarrow \infty} I = \frac{1}{(4\pi)^2} \left(\log x \Lambda^2 - \log \Delta + \mathcal{O}(\Lambda^{-1}) \right)$$

7. Renormalisation

Task: give a physical interpretation for divergencies

7.1. Counting of UV divergences

Example
 QED:  $\sim \int \frac{d^4 k_1 \dots d^4 k_L}{(k_i - m) \dots (k_j^2)}$

Def.: superficial degree of divergence

$$D \equiv (\text{power of } k \text{ in numerator}) - (\text{power of } k \text{ in denominator})$$

$$= 4L - P_e - 2P_\gamma \leftarrow \begin{array}{l} \# \text{ photon propagators} \\ \# \text{ electron propagators} \end{array}$$

\nwarrow # Loops

Naive: Λ^D divergence for $D > 0$ \swarrow often wrong
 cutoff \rightarrow $\log \Lambda$ — " — $D = 0$ \searrow
 \circ no — " — $D < 0$

$$L = P_e + P_\gamma - V + 1 \leftarrow \# \text{ vertices}$$

$$V = 2P_\gamma + N_\gamma = \frac{1}{2} (2P_e + N_e) \leftarrow \# \text{ external legs}$$

$$D = 4 - N_\gamma - \frac{3}{2} N_e$$

only depends on the number of external legs!

Candidates for " primitively " divergent integrals in QED:

a) just shifts vacuum energy

b) = 0 by Lorentz invariance

d) = 0 ———— || ————

f) is finite by symmetry

→ only 3 left, they renormalise the electron's

e) mass and g) coupling to the em field
 ↖ log div. ↖ log div.

and the polarisation of the vacuum c)
